Steady-State Probabilities Transient Analysis Summary Assignment Announcement

Holger Hermanns, Sven Johr:  
Ad-hoc Networking – Models and Methods

Recall Direct Methods Transient Analysis Summary Assignment Announcement

## Steady-State and Transient Behaviour

- Steady-State behavior,
  - DTMC:  $\underline{\pi}P = \underline{\pi}$ ,
  - CTMC: .
- Transient behaviour,
  - DTMC:  $\underline{\pi}(n) = \underline{\pi}(0)P^n$ ,
  - CTMC: , can be solved via  $\underline{\pi}(t) = \underline{\pi}(0)e^{Qt} =$  .
- $\underline{r} = (r_1, r_2, \dots, r_n)$  vector,
  - $\underline{c} = (c_1, c_2, \dots, c_n)^T$  vector,
  - $\underline{\pi}$  probability vector (column or row),
  - $\underline{\pi}(t)$  probability vector at (column or row).

## Use of Direct Methods

- Used to solve systems of linear equations,
  - matrix  $A$ , dimension  $n$ ,
  - vectors  $\vec{x} = (x_1, x_2, \dots, x_n)^T$  and  $\vec{b} = (b_1, b_2, \dots, b_n)^T$ .
- Computing steady-state  $\underline{\pi}M = \underline{0}$ , with
  - for CTMC,
  - for DTMC.
- Rephrasing necessary,
  - .

## Gaussian Elimination – The Method

- Transfer  $A\vec{x} = \vec{b}$  to  $U\vec{x} = \vec{c}$  with,
  - $U$  upper triangular.
- Obtaining  $U$  from  $A$  called
  - $n - 1$  steps,
  - $i^{\text{th}}$  step: eliminate elements below  $i^{\text{th}}$  diagonal element.
- $\vec{x}$  obtained in
  - $x_i = \frac{c_i - \sum_{j=i+1}^n a_{ij}x_j}{a_{ii}}$ ,  $i = n - 1, \dots, 2, 1$ .

## Gaussian Elimination – Reduction Phase

- Elements  $a_{kl}^{(i)}$ ,  $i = 1, 2, \dots, n - 1$ ,
  - $a_{kl}^{(i)} = \frac{c_l - \sum_{j=i+1}^n a_{lj}x_j}{a_{li}}$  for  $k \leq i$ ,  $l = 1, 2, \dots, n$ ,
  - $a_{kl}^{(i)} = \frac{c_l - \sum_{j=i+1}^n a_{lj}x_j}{a_{li}}$  for  $k > i$  and  $l = 1, 2, \dots, n$ .
- Elements  $a_{ii}^{(i)}$  element set to 0.
- $a_{ii}^{(i)} \neq 0$ .
- May be necessary (stability).
- Remark:  $\vec{b}$  has to be scaled accordingly.

## Gaussian Elimination – Markov Chains

- Right hand side equals  $\vec{1}$ .
- Rank of system is  $n - 1$  (one row of matrix is 0),
  - resulting steady-state vector,
  - normalisation equation directly.
- Example:  $Q = \begin{pmatrix} -4 & 2 & 2 \\ 1 & -2 & 1 \\ 6 & 0 & -6 \end{pmatrix}$ ,  $Q^T = \begin{pmatrix} -4 & 1 & 6 \\ 2 & -2 & 0 \\ 2 & 1 & -6 \end{pmatrix}$

## LU Decomposition – The Method

- Write  $A$  as  $A = LU$ ,
  - $A\vec{x} = \vec{b} \Rightarrow L(U\vec{x}) = \vec{b}$ ,
  - $L$  is lower triangular,
  - $U$  is upper triangular.
- Solve  $L\vec{z} = \vec{b}$ ,
  - simple forward substitution.
- Solve  $U\vec{x} = \vec{z}$ ,
  - simple backward substitution.

## LU Decomposition – Computation of $L$ and $U$

- $n^2$  equations,

$$a_{ij} = \dots, \quad i, j = 1, 2, \dots, n. \quad (1)$$

- Find unknowns,
  - $l_{ik}, i = 1, 2, \dots, n,$
  - $u_{kj}, j = 1, 2, \dots, n,$
- Choose  $n$  unknowns,
  - $l_{ij} = 1, 1 \leq i \leq n,$
  - $u_{ii} = 1, 1 \leq i \leq n,$
- Rewrite Equation (1),
  - $i \leq j: a_{ij} = u_{ij} + \sum_{k=1}^{i-1} l_{ik} u_{kj} \Leftrightarrow$
  - $i > j: a_{ij} = l_{ij} u_{jj} + \sum_{k=1}^{j-1} l_{ik} u_{kj} \Leftrightarrow$
  - and solve iteratively.

## LU Decomposition – Comparison to Gauss

- $LU$  decomposition and  $U$  are intimately related.
- $L$  matrix of  $U$  used in Gaussian elimination.
- $U$  upper triangular matrix obtained from  $L$ .
- Benefit,
  - matrix  $L$  available, hence solving for more than one  $U$  quickly possible.

## Iterative vs. Direct Methods

- Result is computed in  $n$  iterations,
  - no precise solution available.
- Number of steps depends on  $n$ ,
  - not a-priori known.
- Efficient  $n \times n$  matrices can be used,
  - sparse matrices,
  - decision diagrams.
- No  $n^2$  operations (see Example).
- Solution of  $n \times n$  systems possible;
  - direct methods  $n^2$  operations to systems with a states/equations.

## Power Method – The Method

- For DTMC,
  - multiply (steady-state) vector  $\underline{x}$  with  $\mathbf{P}$  until  $\underline{x} = \mathbf{P}\underline{x}$ .
- For CTMC,
  - determine DTMC  $\mathbf{P} = \mathbf{I} - \mathbf{Q}\Delta t$ ,  $\lambda \geq \max_i \{|q_{ii}|\}$ .
  - $\underline{x}^{(i)} \mathbf{P} = \underline{x}^{(i+1)}$ .
- Used to solve for left eigenvector with eigenvalue 1.
- Not very efficient.

## Jacobi Method – The Method

- Rewrite  $i^{\text{th}}$  equation:  $p_i = \left( \sum_{j=1}^{i-1} p_j a_{ij} + \sum_{j=i+1}^n p_j a_{ij} \right)$ .
- Use first estimate  $\vec{\pi}^{(0)}$ ,
  - uniform distribution good choice.
- Next estimate
  - $p_i^{(k+1)} = \frac{1}{|a_{ii}|} \left( \sum_{j=1}^{i-1} p_j^{(k)} a_{ij} + \sum_{j=i+1}^n p_j^{(k)} a_{ij} \right)$ .
- Stop iterating: (difference criterion),
  - not necessarily solution vector found!
- Check (residual criterion);
  - more expensive, hence
  - use combination of both.
- Slow conversion: use iterates. on non-successive iterates.

## Gauss-Seidel – The Method

- Structures the Jacobi method,
  - Jacobi method requires storage of two vectors  $\vec{\pi}^{(k)}$  and  $\vec{\pi}^{(k+1)}$ ,
  - now, results are used as soon as computed.
- $p_i^{(k+1)} = \frac{1}{|a_{ii}|} \left( \sum_{j=1}^{i-1} p_j^{(k+1)} a_{ij} + \sum_{j=i+1}^n p_j^{(k)} a_{ij} \right)$ ,
  - order of computation is assumed to be from  $p_1$  to  $p_n$ .
- Storage of only one probability vector.
- Iteration scheme  $D\vec{\pi}^{(k+1)} = L\vec{\pi}^{(k+1)} + U\vec{\pi}^{(k)}$ ,
  - $\vec{\pi}^{(k+1)} = (D - L)^{-1} U \vec{\pi}^{(k)}$ ,
  - iteration matrix  $\Phi_{GS} = (D - L)^{-1} U$ .

## Example

- Reconsider  $Q$  from above examples.
- $\Phi_P = I + Q/\lambda = \frac{1}{6} \begin{pmatrix} 2 & 1 & 6 \\ 2 & 4 & 1 \\ 2 & 1 & 0 \end{pmatrix}$ . 10 iterations.
- $\Phi_J = D^{-1}(L + U) = \begin{pmatrix} 0 & \frac{1}{4} & \frac{3}{4} \\ 1 & 0 & 0 \\ \frac{1}{3} & \frac{1}{6} & 0 \end{pmatrix}$ . 8 iterations.
- $\Phi_{GS} = (D - L)^{-1} U = \begin{pmatrix} 0 & \frac{1}{4} & \frac{3}{4} \\ 0 & \frac{1}{4} & \frac{3}{4} \\ 0 & \frac{1}{6} & 0 \end{pmatrix}$ . 2 iterations.

## The Method

- Solving differential equation system  $\vec{\pi}'(t) = \vec{\pi}(t)Q$ , numerically.
- Approximate  $\vec{\pi}(t)$  by a  $p_i, i \in \mathbb{N}$ ,
  - use  $h$ , hence,
  - $p_i = \vec{\pi}(ih)$ .
- $p_0$  chosen as  $\vec{\pi}(0)$ .
- The smaller  $h$ ,
  - result more accurate,
  - and more expensive.
- $p_i$  is used to compute  $p_{i+1}$ ,
  - but not  $p_0$  to  $p_{i-1}$ , method.
- Fairly efficient.
- Methods of different order exist.

## Main notion

- Solution via expansion for generator matrix  $Q$ 
  - $\underline{\pi}(t) = \underline{\pi}(0)e^{Qt}$  not applicable,
    - infinite summation cannot be severe (positive and negative entries of  $Q$ ).
- Overcome this by
- Define
  - $\lambda \geq \max_i \{|q_{ii}|\}$  called
- $P$
- $\underline{\pi}(t) = \underline{\pi}(0)e^{Qt} = \underline{\pi}(0)e^{-\lambda t} e^{\lambda Pt}$
- $\underline{\pi}(t) =$

## Benefit

- Still dealing with Taylor series.
- All values are between 0 and 1.
- Allows for iterative solution,
  - $\underline{\pi}(t) = \sum_{n=0}^{\infty} \psi(\lambda t; n) (\underline{\pi}(0)P^n) =$
  - $\underline{\pi}_n$  computed recursively ( $\underline{\pi}_0 = \underline{\pi}(0)$ ).
- Sum is after steps,
  - $k_\epsilon$  is computed a-priori with respect to accuracy  $\epsilon$ ,
  - $\|\underline{\pi}(t) - \underline{\pi}(t)\| \leq 1 - \sum_{n=0}^{k_\epsilon} \psi(\lambda t; n)$
  - $\sum_{n=0}^{k_\epsilon} \frac{(\lambda t)^n}{n!} \geq \frac{1-\epsilon}{e^{\lambda t}} = (1-\epsilon)e^{-\lambda t}$ .
- For large  $\lambda t$ ,
  - steady-state reached? Stop computing

## Main Computational Challenges

- Steady-state analysis, ( $A\vec{\pi} = \vec{0}$ )
  - DTMC: product with until convergence,
  - CTMC: product with until convergence.
- Transient analysis,
  - DTMC: matrix-vector product, ( $\underline{\pi}(n) = \underline{\pi}(n-1)P$ )
  - CTMC: uniformisation, summation over with

## Uniformisation

- Consider  $Q = \begin{pmatrix} -3 & 2 & 0 & 1 \\ 0 & -4 & 1 & 3 \\ 1 & 0 & -1 & 0 \\ 0 & 2 & 0 & -2 \end{pmatrix}$ .
- Assume  $\underline{\pi}(0) = (1, 0, 0, 0)$ .
- Compute the probability distribution for  $t = 1$  with uniformisation and answer thereby the following questions.
  - How large is the uniformisation rate  $\lambda$ ?
  - How large is  $k_\epsilon$  for  $\epsilon = 10^{-n}$ ,  $n = 1, 2, 3, 4, 5$ ?
